

# THE EXACT ONLINE AGENT

What it will do, how it works,  
and what it needs to get started

**DRAFT FOR DISCUSSION**

Version 0.4 · 25 September 2026

Prepared by Siddhartha Sharma, Data and Decision Scientist

## »»» 01

## SUMMARY

The Exact Online agent is an AI agent that will look after Inbox Storage's bookkeeping data the way a small finance-operations team would. It keeps postings clean and reconciled, keeps the chart of accounts and VAT setup documented, answers financial questions using agreed definitions, and watches receivables, payables and cash before problems grow. It is the third department agent on the shared platform, after HubSpot and Shiftbase. Because it sits closest to statutory reporting, VAT and cash, it is the most conservative of the three: it never writes to Exact.

| Job                                | What it means in practice                                                                                                                                                                                    |
|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Keep postings clean                | Checks written rules every day (unposted entries, unmatched bank lines, postings to the wrong type of account, VAT codes that don't fit the account, duplicate suppliers) and records each problem it finds. |
| Keep the setup lean and documented | Takes a nightly copy of the chart of accounts, VAT codes, cost centres and journals, flags any change to the setup, and suggests which unused ledgers can be deleted or blocked.                             |
| Answer questions                   | Answers questions about revenue, cost, margin and cash from colleagues and other agents, and names the definition it used.                                                                                   |
| Watch cash and compliance          | Tracks ageing, overdue amounts, payments that could settle open items, money owed back to customers, changed supplier bank details, VAT deadlines and period-close readiness.                                |
| Work with other agents             | Checks a HubSpot deal marked won against the revenue actually booked, or Shiftbase hours against wage cost in the ledger, by asking and answering the other agents.                                          |

## HOW IT WORKS, IN ONE PARAGRAPH

The agent reads Exact data from Snowflake rather than from Exact itself, and runs on a schedule as a set of small, single-purpose skills. It has no permission to change anything in Exact: it produces findings, change requests and draft lists, a bookkeeper applies any change in Exact, and the next data load confirms that it landed. Every run and every decision is logged, and the knowledge, rules and nightly configuration history live in a GitHub repository that also serves as the recovery kit.

**Starting point.** The administration has 636 GL accounts and 17 VAT codes, with 11,199 receivable lines and 234 payable lines open. The Sales Invoice module holds only 81 invoices, the latest from 2018: day-to-day storage revenue is posted straight to the ledger, so the agent reads revenue from transaction lines. Only the revenue lines of four accounts and a few monthly summaries reach Snowflake today, from exports. Section 2 has the details; section 11 lists the decisions needed to start.

## »»» 02

## STARTING POINT

Before designing anything, I checked which Exact Online modules and data are actually in use, how complete the records are, what already reaches Snowflake, and what Claude's Exact Online connector can do. All figures were measured on 25 September 2026 in the Inbox Storage BV administration.

| What I checked           | What I found                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Chart of accounts        | 636 GL accounts.                                                                                                                                                                                                                                                                                                                                                                                                      |
| VAT codes                | 17 VAT codes.                                                                                                                                                                                                                                                                                                                                                                                                         |
| Open receivables         | 11,199 open invoice lines (Exact statuses 20 and 30, which mark open items). Money received but not yet matched to any invoice is not in this list: Exact keeps it in a separate list, so the real matching backlog is larger. At this volume a materiality threshold is needed, or every small open item becomes a finding.                                                                                          |
| Open payables            | 234 open invoice lines (statuses 20 and 30).                                                                                                                                                                                                                                                                                                                                                                          |
| History                  | The ledger goes back to 2007.                                                                                                                                                                                                                                                                                                                                                                                         |
| Sales invoices           | Only 81 invoices in the Sales Invoice module, the latest from 2018 and none in 2026. Recurring storage revenue (the thousands of lines on GL 8000, 8001, 8020 and 8021) is posted directly to the ledger, most likely by the billing system's integration. The agent therefore reads revenue from transaction lines, not from invoices.                                                                               |
| Customer link            | In the GL exports, Exact's relation number is the same as the Striker customer code, which Bumbal also uses. Exact joins the other systems without any fuzzy matching.                                                                                                                                                                                                                                                |
| Fixed assets             | This connection has no read rights on the assets endpoint, so it is not yet clear whether the Fixed Assets module is used. To confirm with the account owner.                                                                                                                                                                                                                                                         |
| Data in Snowflake        | Partly. The revenue lines of GL 8000, 8001, 8020 and 8021 for Inbox Storage (21,815 lines) and monthly revenue summaries for both brands (top five accounts, revenue per product) are in the EXACT database, last updated 21 September. They appear to come from the exports used for the revenue analyses, not from a scheduled loader.                                                                              |
| Claude's Exact connector | Reads the live administration and keeps its own analysis copy, on a trial with full access until 25 October 2026. Its copy of transaction lines has so far synced 2007 to 2021 (325,000 lines); receivables, bank and period data are still syncing, while GL accounts, journals, cost centres, VAT codes, payment terms, customers, suppliers and items are complete. It can also create, change and delete records. |
| API limits               | 60 calls per minute and 5,000 per day per administration; a new access token at most every 10 minutes; more than 10 errors per endpoint in an hour blocks the key for a while. Exact's sync endpoints return only what changed since a given moment, which keeps nightly loads well inside these limits.                                                                                                              |

## »»» 03

## WHAT THE AGENT WILL DO

### KEEP POSTINGS CLEAN

Every weekday the agent evaluates written hygiene rules against the latest data: unposted or draft entries, bank lines not yet matched, postings to the wrong type of account (revenue on a cost account, or the reverse), VAT codes that don't fit the account's normal VAT treatment, duplicate supplier records, missing cost centres, and amounts left in a suspense account beyond an agreed number of days. Each rule is a file with an owner, a severity and an agreed threshold, and every change to a rule creates a new version.

## WHAT HAPPENS TO A FINDING: TRIAGE

In a step called **triage**, the agent goes through each new finding and makes one of four decisions: set it aside as expected or harmless, with the reason written down; escalate it to a person; propose a fix as a change request for the bookkeeper; or ask another agent to check it against its own system.

Near-identical findings are handled as one group, so open receivables below the materiality threshold become one summary line rather than thousands of items. Every triage decision is recorded with its reason.

## KEEP THE SETUP DOCUMENTED

Each night the chart of accounts, VAT codes, cost centres, cost units and journals are copied into GitHub, so comparing one night with the next shows exactly what changed. The agent flags new or unused GL accounts, overlapping VAT codes, changes to journal setup, and customers or suppliers on non-standard payment terms, since every ageing figure depends on them. Structural changes stay with people: the agent recommends, and someone with Exact admin rights decides and acts.

## CLEAN UP UNUSED LEDGERS

A chart of 636 accounts almost certainly carries accounts nobody posts to any more, and each one is a chance to book something in the wrong place. Every quarter, and before the year-end close, the agent produces a **ledger clean-up list**: which accounts are unused, the evidence for each, and what it suggests doing. An account only counts as unused if all of these hold:

| Test                                                                        | Why it matters                                                                                                                                                                                                                               |
|-----------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>No postings in the last 24 months, ignoring year-end closing entries</b> | Two full years, so accounts used only in one season or at year end are never caught by mistake. Closing entries don't count: Exact books one against every profit-and-loss account each year, which would make every such account look used. |
| <b>A zero balance</b>                                                       | An account with money on it can't be retired until the balance is cleared or moved.                                                                                                                                                          |
| <b>Not referenced anywhere in the setup</b>                                 | VAT codes, journals, items, bank and cash journals, default accounts (rounding, exchange differences, suspense), recurring entries and budgets can all point to an account.                                                                  |
| <b>Not used by the billing integration</b>                                  | The integration posts storage revenue from outside Exact, so Exact can't see its mapping. The accounts it uses are listed in the knowledge repo and never suggested.                                                                         |

Each account on the list shows its last posting date, how many lines were ever posted to it, its balance, any references found and the reporting line it rolls into. The suggestion depends on what the evidence shows:

| What the evidence shows                                                             | Suggestion                                                                                                                                                                                        |
|-------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Never posted to, and not referenced anywhere</b>                                 | <b>Delete.</b> Nothing depends on it, and the nightly snapshot can recreate it if needed.                                                                                                         |
| <b>Posted to in the past, but unused for 24 months, zero balance, no references</b> | <b>Block for new postings</b> rather than delete. Its history stays intact: Dutch bookkeeping records must be kept for seven years, and accounts with postings generally can't be deleted anyway. |
| <b>Unused, but still carrying a balance</b>                                         | <b>Clear the balance first</b> (reclassify or write off, as the finance owner decides), then it reappears on the next list.                                                                       |
| <b>Unused, but still referenced in the setup</b>                                    | <b>Keep</b> , and show where it is referenced. If it should go, the reference is removed first.                                                                                                   |

| What the evidence shows         | Suggestion                                                        |
|---------------------------------|-------------------------------------------------------------------|
| Two accounts doing the same job | <b>Merge:</b> point future postings to one, then block the other. |

The same test runs over cost centres, cost units, VAT codes and journals. The agent never deletes or blocks anything itself: the finance owner, ideally with the external accountant, approves the list, and someone with Exact admin rights acts on it. The next night's snapshot records exactly what changed.

## CHECK THE REPORTING MAPPING

Every GL account rolls into a line of the financial statements through Exact's reporting classifications. An account that isn't mapped, or is mapped to the wrong line, puts money in the wrong place in the annual accounts. The agent checks that every active account is mapped in the scheme the accountant uses (the Dutch reference chart of accounts, RGS, if that is the one), and flags any new account that arrives without a mapping.

## ANSWER QUESTIONS, FOR PEOPLE AND FOR OTHER AGENTS

The agent keeps a dictionary of what each account type and metric means, starting from the definitions already used for the GL 8000-series revenue analysis (revenue means profit-and-loss accounts of the revenue type; in Exact terms, BalanceType W and Type 110). It answers questions with those definitions and always names the one it used. Other agents ask through a named capability, *finance.lookup*, without needing to know how Exact is set up.

## WATCH CASH AND COMPLIANCE

The agent tracks receivables and payables ageing, flags overdue amounts above agreed thresholds, projects the short-term cash position from open items and recurring postings, and tracks VAT deadlines and period-close readiness. The finance owner receives these as totals with recommended next steps, not as lists of individual transactions to chase by hand.

## MATCH OPEN ITEMS

Exact keeps two lists apart: open invoices (the 11,199 lines) and money received that hasn't been matched to any invoice. Each unmatched receipt that belongs to an open invoice makes the ageing figures look worse than they are. The agent pairs the two lists: for every unmatched receipt it looks for open invoices of the same customer that fit by amount and date, and proposes the match to the bookkeeper with its confidence. In Exact a match is recorded as a match set, which the bookkeeper creates.

## CHECK BILLING AGAINST THE LEDGER

Storage revenue reaches Exact through the billing integration, so a failed or partial sync would silently understate revenue. Each month the agent compares what the billing system invoiced with what was posted, per revenue account and per customer code, asking the agent responsible for subscriptions and billing for its totals. Any gap is a finding, raised before the month is closed.

## SPOT MONEY OWED BACK TO CUSTOMERS

When a customer ends a storage contract, a credit balance can remain on their account, for example after a prepayment or a duplicate payment. The agent lists customer accounts in credit for longer than an agreed period, as totals and customer codes, so refunds are made rather than forgotten.

## **WATCH SUPPLIER BANK DETAILS**

A changed bank account on a supplier just before a payment run is a classic fraud pattern. The agent flags new suppliers and any change to a supplier's bank details, so the change can be confirmed with the supplier by phone before money goes out. To do this without storing bank details, the loader keeps only a fingerprint of each account number: a change is visible, but the number itself never leaves Exact. When a supplier invoice arrives as an e-invoice, it carries the bank account to pay; the agent compares its fingerprint with the supplier's registered account and flags any difference before the payment run.

## **CHECK SUPPORTING DOCUMENTS**

Every purchase entry should have the supplier's invoice attached: the accountant needs it, and VAT can only be reclaimed with a valid invoice. The agent lists purchase entries without a document, and entries whose attached e-invoice doesn't match what was booked (amount, VAT or due date).

## **PREPARE THE ACCOUNTANT'S PACK**

Before the year-end close, the agent assembles what the external accountant usually asks for: the trial balance, the status of every reconciliation, open items by age, a list of manual journal entries above a threshold, and every change to the chart of accounts during the year, taken from the nightly snapshots. It turns weeks of back-and-forth into one reviewed file.

## **WORK WITH THE OTHER DEPARTMENT AGENTS**

When an answer depends on another system, the agent asks that system's agent, and answers their questions in turn. A HubSpot deal marked won with no matching revenue posting becomes a reconciliation request answered here. Shiftbase's registered hours can be set against wage cost in the ledger, and Bumbal job volumes against logistics costs. Requests and replies are typed messages stored in Snowflake, so every exchange between agents is on record.

# **A DAY IN THE LIFE**

The agent's work is split into scheduled tasks. Times below are proposals.

| When                                   | What runs                                                                                                                                      | What comes out                                                           |
|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------|
| Every night                            | Load Exact data into Snowflake; copy the chart of accounts, VAT codes and journals to GitHub; export yesterday's runs and decisions to GitHub. | Fresh data, configuration history, audit trail                           |
| Weekday mornings                       | Ageing pass: refresh receivables and payables ageing and draft a prioritised reminder list.                                                    | Ageing overview; draft reminder list for approval                        |
| Weekdays, end of day                   | Daily upkeep: evaluate rules, triage findings, draft change requests, post the summary.                                                        | Findings, decisions, change requests for the bookkeeper, a Slack summary |
| Weekly                                 | Refresh the cash forecast and the margin and trend figures.                                                                                    | Short-term cash projection, trend charts                                 |
| Monthly                                | Billing-to-ledger check: revenue invoiced by the billing system against revenue posted.                                                        | Findings for any gap, before the month closes                            |
| Before each VAT filing or period close | Close checklist: everything that would block a clean close or filing, grouped by owner.                                                        | One checklist, cleared before the deadline                               |
| Quarterly and before year end          | Ledger clean-up: unused accounts, cost centres, VAT codes and journals, with evidence and a suggestion for each.                               | A clean-up list for the finance owner to approve                         |
| Year end                               | Accountant's pack: trial balance, reconciliation status, open items, manual journals, chart-of-accounts changes.                               | One reviewed file for the external accountant                            |
| Hourly, office hours                   | Inbox: answer messages from other agents.                                                                                                      | Replies to other agents                                                  |

after = order only    requires = run only if the previous step succeeded

Figure 1. The daily upkeep task. Each step is a separate skill. "Draft fixes" here means change requests for the bookkeeper; the agent never posts in Exact. If a step can't run it is skipped with a logged reason and the rest carry on.

The daily summary tells the finance owner what was found and closed today, what the agent decided, which change requests are waiting for the bookkeeper, and whether any step was skipped and why. It carries a run number, so anyone can look up exactly what happened in that run.

# HOW IT'S BUILT

The agent uses the same platform as the HubSpot and Shiftbase agents: shared Snowflake tables for runs and decisions, the same task runner and the same independence checks. It is made of skills that each do one job and can be added, switched off or removed without breaking the others. Thirty-one skills are proposed in four groups. Not all are needed at once: the column on the right shows the roadmap phase (section 10) in which each one arrives.

Figure 2. The hierarchy. The platform is shared by all agents; the Exact Online agent is its own repository and plugin; agents cooperate only through messages.

## DATA FOUNDATION (EXTERNAL)

| Skill                  | Job                                                                                                                                            | Phase |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| exact-loader           | Land GL transactions, receivables, payables and unmatched receipts in Snowflake, read-only, using Exact's sync endpoints within the API limits | 1     |
| exact-master-data-sync | Load customers, suppliers, items, price lists, cost centres and cost units                                                                     | 1     |
| exact-config-snapshot  | Nightly copy of the chart of accounts, VAT codes, journals and cost centres to GitHub                                                          | 1     |
| exact-audit-export     | Nightly export of runs, decisions and change requests to GitHub                                                                                | 1     |
| exact-rate-table-sync  | Load exchange rates, if foreign-currency postings exist                                                                                        | 4     |

**MONITORS (SNOWFLAKE)**

| Skill                                    | Job                                                                                                                                                                                            | Phase |
|------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| <b>exact-hygiene-monitor</b>             | Posting rules: unposted entries, wrong account type, VAT mismatches, missing cost centres                                                                                                      | 2     |
| <b>exact-setup-monitor</b>               | Chart-of-accounts changes, overlapping VAT codes, journal changes, reporting-mapping gaps, non-standard payment terms, and usage evidence for every account, cost centre, VAT code and journal | 2     |
| <b>exact-aging-monitor</b>               | Receivables and payables ageing against agreed thresholds                                                                                                                                      | 2     |
| <b>exact-bank-reconciliation-monitor</b> | Unmatched bank lines and old suspense-account balances                                                                                                                                         | 2     |
| <b>exact-period-close-monitor</b>        | Periods open past their close date, missing accruals, unposted month-end journals                                                                                                              | 4     |
| <b>exact-duplicate-invoice-detector</b>  | Possible duplicate purchase or sales invoices by party, amount and date                                                                                                                        | 4     |
| <b>exact-open-item-matcher</b>           | Unmatched receipts that fit an open item by customer, amount and date                                                                                                                          | 4     |
| <b>exact-credit-balance-monitor</b>      | Customer accounts in credit for longer than agreed (refunds owed)                                                                                                                              | 4     |
| <b>exact-supplier-change-watch</b>       | New suppliers, changed bank details, and e-invoices whose bank account differs from the supplier's, using fingerprints only                                                                    | 4     |
| <b>exact-document-check</b>              | Purchase entries without a supporting document, or whose e-invoice differs from the booking                                                                                                    | 4     |
| <b>exact-multicurrency-monitor</b>       | Unrealised exchange differences and missing rates, if needed                                                                                                                                   | 4     |
| <b>exact-anomaly-detector</b>            | Unusual postings (amounts, timing, round numbers) for review; report-only                                                                                                                      | 6     |

**DECISION AND WORKFLOW (CLAUDE)**

| Skill                               | Job                                                                                                                      | Phase |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------|-------|
| <b>exact-finding-triage</b>         | Decide what to do with each finding (triage)                                                                             | 3     |
| <b>exact-change-proposals</b>       | Turn fix decisions into change requests for the bookkeeper                                                               | 3     |
| <b>exact-query-desk</b>             | Answer financial questions from people and other agents, naming the definition                                           | 3     |
| <b>exact-daily-summary</b>          | Post the end-of-day summary to Slack                                                                                     | 3     |
| <b>exact-ledger-cleanup-advisor</b> | Turn usage evidence into the quarterly clean-up list: delete, block, clear first, keep or merge                          | 3     |
| <b>exact-collections-assistant</b>  | Draft a prioritised reminder list for overdue receivables; never sends anything                                          | 4     |
| <b>exact-reconciliation</b>         | Cross-agent checks: HubSpot deals against revenue, Shiftbase hours against wage cost, Bumbal jobs against logistics cost | 5     |
| <b>exact-billing-reconciliation</b> | Monthly check of revenue invoiced by the billing system against revenue posted, per account and customer code            | 5     |

**ANALYSIS AND FORECASTING (SNOWFLAKE AND CLAUDE)**

| Skill                               | Job                                                                                   | Phase |
|-------------------------------------|---------------------------------------------------------------------------------------|-------|
| <b>exact-margin-analyst</b>         | Revenue, cost and margin per account or service line, using the agreed definitions    | 4     |
| <b>exact-cashflow-forecaster</b>    | Short-term cash projection from open items and recurring postings                     | 4     |
| <b>exact-vat-compliance-checker</b> | VAT deadlines, VAT code coverage, and VAT-number checks for any cross-border invoices | 4     |
| <b>exact-month-end-checklist</b>    | The close-readiness checklist for the finance owner before cut-off                    | 4     |
| <b>exact-benchmark-tracker</b>      | Trend lines for hygiene, ageing and margin, so slow deterioration shows               | 6     |
| <b>exact-accountant-pack</b>        | Year-end pack for the external accountant, from ledger data and snapshots             | 6     |

WHY REMOVING A SKILL DOESN'T BREAK THE OTHERS

Skills never call each other. Each one declares what it reads and writes and depends only on that data, and agents address each other by capability, not by name. The same checker used for the HubSpot agent will show what removing any skill or agent affects before anyone does it. The expected results:

| Remove                      | Verdict  | Because                                                                                    |
|-----------------------------|----------|--------------------------------------------------------------------------------------------|
| The daily summary           | Safe     | Only the task file needs a one-line edit.                                                  |
| The collections assistant   | Safe     | Ageing findings still exist; only the drafted reminder list disappears.                    |
| The ledger clean-up advisor | Safe     | Usage evidence is still produced by the setup monitor; only the quarterly list disappears. |
| The reconciliation skill    | Degrades | Reconciliation requests from other agents go unanswered; nothing else stops.               |
| Finding triage              | Breaks   | Change proposals and the collections assistant lose the decisions they work from.          |
| The loader                  | Breaks   | Every monitor, the query desk and the analysis skills lose their data.                     |

Expected verdicts, to be confirmed with the checker once the skill definitions exist.

EVERYTHING FLOWS THROUGH SNOWFLAKE

Figure 3. Data flow. Exact data lands in Snowflake; the agent reads and logs there; any change in Exact is made by the bookkeeper and confirmed by the next load.

**EXACT.RAW** keeps every version of every record it loads, giving full history even where Exact itself only shows the current state. **EXACT.CORE** turns that into clean views for the agent and Power BI, including the revenue and cost views already used for the GL 8000-series analysis. **EXACT.GOVERNANCE** holds the versioned account-type dictionary. **INTEGRATION** extends the customer link used by the HubSpot

agent (HubSpot contact to Striker customer code); because Exact's relation number is that same code, one customer can be followed from first contact to revenue to payment. **AGENT\_OPS** is the schema shared by all agents: this agent adds rows, not tables.

Exact is read only by the loader. The agent itself works from Snowflake, so heavy questions never slow down Exact for the people using it.

»»» 07

## SAFEGUARDS

Postings feed statutory reporting and VAT filings, which puts this agent closer to Shiftbase's payroll risk than to HubSpot's CRM risk. So there is deliberately no skill that writes to Exact.

| Level          | What                                                                                              | Who acts                                                |
|----------------|---------------------------------------------------------------------------------------------------|---------------------------------------------------------|
| 0 · Report     | Read, measure, report, raise findings                                                             | The agent, on its own                                   |
| 1 · Propose    | Draft a bank-line match, a reclassification or a reminder list, as a change request or draft only | A bookkeeper applies it in Exact; the agent never posts |
| 2 · Structural | New GL accounts, VAT code changes, chart-of-accounts restructuring, journal setup                 | A person, in Exact; the agent only recommends           |

| Safeguard                           | What it means                                                                                                                                                                                                                            |
|-------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Read-only connection                | The loader connects with read-only rights and only sends read requests; an automatic check rejects any code that tries to write.                                                                                                         |
| Before and after                    | Every change request records the current and the proposed value, so the next load shows whether what the bookkeeper applied matches what was proposed.                                                                                   |
| No bank or personal details in logs | Bank account numbers, IBANs and customers' or suppliers' personal details never go into logs or GitHub. Records hold IDs, codes and counts, and an automatic check blocks anything that looks like an IBAN, card number or access token. |
| Payroll postings                    | Wage-cost postings can show what an individual earns. The loader keeps wage-cost accounts at account and period level without line descriptions, and cross-checks with the Shiftbase agent use totals only.                              |
| Reminders are drafts                | The collections assistant drafts a list; a person decides what is sent, and sends it.                                                                                                                                                    |
| Clean-up is advice                  | The agent never deletes or blocks an account. Each suggestion carries its evidence, the finance owner approves the list, and a deleted account can be recreated from the nightly snapshot.                                               |
| Bank details as fingerprints        | Supplier bank account numbers are never stored; only a fingerprint that shows when one has changed.                                                                                                                                      |
| The Exact connector                 | Claude's Exact Online connector can create, change and delete records. None of the agent's skills use it: they read from Snowflake. For ad-hoc questions, its write tool should be switched off where the settings allow.                |
| A third-party copy                  | The connector keeps a synced copy of the administration at its provider. Before relying on it after the trial, a data-processing agreement should be in place.                                                                           |
| Anomalies are for review            | The anomaly detector only reports. Its findings point to entries, not to the people who made them, and they go through normal triage like any other finding.                                                                             |

## EVERY DECISION IS TRACEABLE

Each run is recorded before any work starts, so a run that crashes shows up instead of disappearing. Every query is logged with its SQL, and every decision with the options considered, what was chosen, why, how confident the agent was and which version of which rule was involved. Each run also records the exact version of the agent's code and rules it used.

When something looks wrong, the run number in the Slack post opens a timeline of that run, and the failing step shows its query. From there it is clear whether the problem was the data (a late or failed load), the rule (which version produced the finding) or the agent's judgment (its written reason). All three agents write to the same tables, so the same trace works everywhere.

## KNOWLEDGE, RECOVERY AND MIGRATION

A private GitHub repository holds everything *about* Inbox Storage's Exact Online environment: the account-type dictionary and rules, plain-language descriptions of each monitor, the nightly configuration history, a daily export of runs and decisions, the recovery runbook and the migration plan. Customers' and suppliers' personal data are kept out of it; the record history lives in Snowflake instead.

| If this happens                                                | Restore from                                                                                   | Data at risk*     | Back in*        |
|----------------------------------------------------------------|------------------------------------------------------------------------------------------------|-------------------|-----------------|
| <b>A GL account, VAT code or journal is deleted or changed</b> | Configuration history in GitHub                                                                | 24 hours          | 1 hour per item |
| <b>Values are overwritten by a bad import</b>                  | Record history in Snowflake                                                                    | One load interval | 4 hours         |
| <b>An entry is reversed, changed or deleted by mistake</b>     | The bookkeeper corrects it in Exact, using the Snowflake history as the record of the original | One load interval | 1 day           |
| <b>An integration breaks or a token is revoked</b>             | Renew the connection, re-run the loads                                                         | None              | Hours           |
| <b>Exact Online is unavailable</b>                             | Nothing to restore: work from Snowflake, pause change requests                                 | None              | —               |

\* Proposed targets, to be agreed. Corrections in Exact go through the same change-request route as any other change. Restores will be rehearsed each quarter in a test administration.

The same repository keeps Inbox Storage ready to move off Exact Online if it ever needs to: a vendor-neutral description of the chart of accounts and account-type conventions, a mapping from each Exact field to it, and full history in Snowflake that doesn't depend on Exact being reachable. GL codes don't carry over between systems, so it is the mapping, not the codes, that makes a future migration manageable.

# ROADMAP

**Already in place from the HubSpot and Shiftbase work.** The shared platform design (run and decision tables, task runner, independence checker) and the personal-data check. Nothing runs against Exact or Snowflake yet for this agent.

| Phase                                    | What gets built                                                                                                                                                                                                                     | What it unlocks                                                          |
|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------|
| <b>1 • Data foundation</b>               | Loader, master-data sync, configuration snapshot and audit export on Exact's sync endpoints, replacing today's exports; field allowlist; clean EXACT.CORE views                                                                     | Revenue, cost and margin in Snowflake and Power BI                       |
| <b>2 • Rules and monitors</b>            | Account-type dictionary; first ten rules with owners and thresholds (hygiene, setup, ageing, bank reconciliation); usage evidence for every account; rule evaluation in Snowflake                                                   | Daily findings with a baseline                                           |
| <b>3 • Agent in operation</b>            | Triage, change proposals, query desk, daily summary and the first ledger clean-up list; scheduled tasks; Slack channel                                                                                                              | The daily cycle in section 4; a leaner chart of accounts                 |
| <b>4 • Cash, compliance and analysis</b> | Collections assistant, open-item matching, credit balances, supplier bank-detail watch, supporting-document check, cash forecaster, VAT compliance, period close, margin analyst, duplicate invoices; multi-currency only if needed | Truthful ageing, early warning on cash, fraud and filing risk            |
| <b>5 • Across systems</b>                | Billing-to-ledger check; reconciliation with the HubSpot, Shiftbase and Bumbal agents                                                                                                                                               | Revenue that provably matches billing; one customer from lead to payment |
| <b>6 • Recovery and refinement</b>       | Restore rehearsals; accountant's pack; anomaly detector and benchmark tracker once there is enough history                                                                                                                          | A smoother year-end; recovery targets that can be relied on              |

## DECISIONS NEEDED

| Decision                                                    | Why it matters                                                                                | Suggestion                                                                                 |
|-------------------------------------------------------------|-----------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------|
| Who owns the account-type dictionary and rule thresholds?   | Every answer and every rule depends on it                                                     | A named finance owner                                                                      |
| Who applies proposed bank matches and reclassifications?    | The agent has no write access, by design                                                      | The current bookkeeper                                                                     |
| What is the materiality threshold for open receivables?     | 11,199 open lines need a cut-off to be useful                                                 | Agree an amount and an age                                                                 |
| How long must an account be unused before it is suggested?  | Too short a window catches seasonal and year-end accounts                                     | 24 months                                                                                  |
| Who approves the ledger clean-up list?                      | Deleting or blocking accounts changes how reports add up                                      | The finance owner with the external accountant, quarterly and at year end                  |
| Which accounts does the billing integration post to?        | Exact can't see the mapping, so those accounts must be protected by hand                      | Document the mapping in the knowledge repo                                                 |
| Is the Fixed Assets module in use?                          | Decides whether the loader covers assets; there is no read access yet                         | Confirm with the account owner                                                             |
| Is the billing integration the source of truth for revenue? | Only 81 sales invoices exist, none since 2018                                                 | Confirm, and document the integration                                                      |
| Are there foreign-currency or cross-border postings?        | Decides whether the multi-currency and VAT-number checks are needed                           | Check before phase 4                                                                       |
| Where does the VAT deadline calendar come from?             | It drives the VAT compliance checks                                                           | The accountant's filing calendar                                                           |
| Who receives the draft reminder list?                       | The agent drafts; it never sends                                                              | The finance owner or credit control                                                        |
| After how long should a credit balance be refunded?         | Sets when money owed back becomes a finding                                                   | 30 days after the contract ends                                                            |
| Which machine runs the nightly jobs?                        | Snowflake only accepts known IP addresses                                                     | The ETL machine used by the other agents                                                   |
| Is Kubox a separate administration in Exact?                | Kubox revenue summaries exist, but the connector only covers Inbox Storage BV                 | Include every administration in the loader                                                 |
| Keep the Exact connector after the trial (25 October)?      | Useful for ad-hoc questions, but it is a paid third-party copy of the ledger and it can write | Only with a data-processing agreement and write access off; the agent doesn't depend on it |
| Which reporting scheme must every account map to?           | Drives the reporting-mapping check                                                            | The one the accountant uses for the annual accounts                                        |
| Are budgets kept in Exact?                                  | Decides whether budget against actual can be added to the margin analysis                     | Check with the finance owner                                                               |

# GLOSSARY

| Term                           | Meaning                                                                                                                                   |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <b>GL account</b>              | A single ledger account in the chart of accounts, such as GL 8000.                                                                        |
| <b>Account type</b>            | Exact's classification of a GL account (revenue, cost, balance sheet and so on), the basis for the agreed revenue and cost definitions.   |
| <b>Ageing</b>                  | How long an open receivable or payable has been outstanding, grouped into bands such as 0–30, 31–60 and over 60 days.                     |
| <b>Materiality threshold</b>   | The amount or age below which open items are summarised rather than listed one by one.                                                    |
| <b>Reconciliation</b>          | Matching two records that should agree: a bank line and a posting, or a deal and the revenue booked for it.                               |
| <b>Reminder (dunning)</b>      | A message to a customer about an overdue amount, usually escalating in tone.                                                              |
| <b>Suspense account</b>        | A holding account for postings not yet classified to their final GL account.                                                              |
| <b>Blocking an account</b>     | Stopping new postings to a GL account while keeping its history, used instead of deleting an account that has been posted to.             |
| <b>Open-item matching</b>      | Linking a payment to the invoice or item it settles, so the item is no longer open.                                                       |
| <b>Credit balance</b>          | A customer account where more has been paid than is owed: money owed back.                                                                |
| <b>Fingerprint</b>             | A code calculated from a value, such as a bank account number, that shows when it changes without storing the value itself.               |
| <b>Match set</b>               | Exact's record that a payment and one or more invoices settle each other.                                                                 |
| <b>Year-end closing entry</b>  | The entry Exact makes when a financial year is closed, moving every profit-and-loss account's result to the balance sheet.                |
| <b>Reporting scheme</b>        | The mapping of GL accounts to the lines of the financial statements, such as the Dutch reference chart of accounts (RGS).                 |
| <b>Sync endpoint</b>           | An Exact API endpoint that returns only records changed since a given moment.                                                             |
| <b>Period close</b>            | Locking a financial period once its postings are final, so it can no longer change silently.                                              |
| <b>VAT-number check (VIES)</b> | The EU system for validating a VAT number, used for cross-border invoices.                                                                |
| <b>Rule</b>                    | A written, versioned check with an owner and a threshold.                                                                                 |
| <b>Finding</b>                 | One problem found by a rule, tracked until it is resolved.                                                                                |
| <b>Triage</b>                  | The step where the agent decides, for each finding, whether to set it aside, escalate it, propose a fix or ask another agent to check it. |
| <b>Change request</b>          | A proposed change with the current and proposed value, waiting for a person to apply it.                                                  |
